

# MONOCLONAL ANTIBODY THERAPY

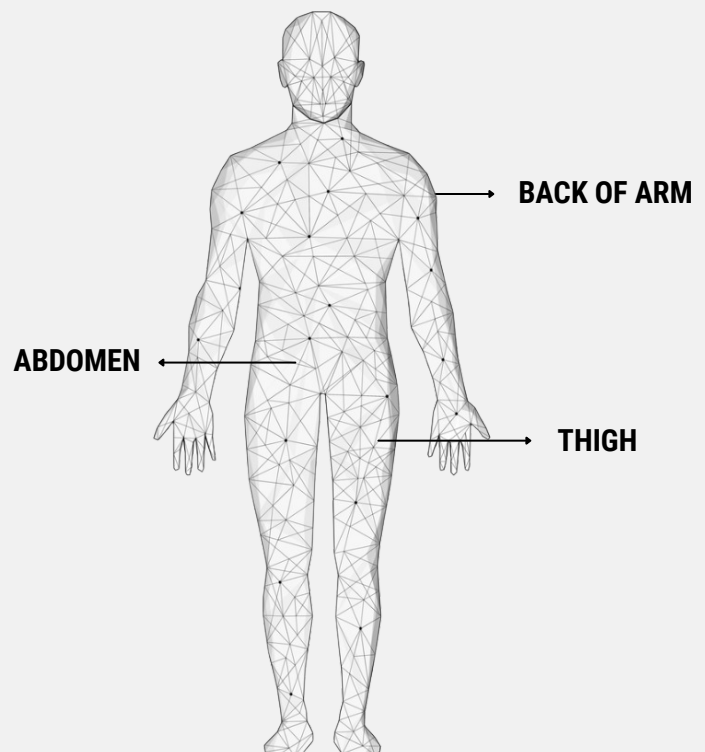

Monoclonal antibodies help your body fight off COVID-19 and are intended to prevent progression of disease and reduce the risk of hospitalization or death. Monoclonal antibodies are most effective when given early in infection. The monoclonal antibody treatment you receive at CDR Health will be administered via subcutaneous injection or IV infusion, and you are encouraged to receive this treatment on a full stomach.

---

## STEP 1: TREATMENT

Treatment will be administered via subcutaneous injections, in the common locations shown, or via IV infusion.

Treatment will take approximately 20 minutes for subcutaneous injections, and approximately 1 hour for IV infusion.

---

## STEP: 2 OBSERVATION

Once treatment is completed, you will be **observed** in the observation unit for **approximately 60 minutes**.

---

Following treatment, it is important to continue self-isolation until:

- 10 or more days have passed since you developed symptoms of COVID-19
- You are fever-free for 24 hours without the use of fever-reducing medicine such as ibuprofen
- Your COVID-19 symptoms are improving
